Bala distributes **C** chocolates to the school for **N** students every Friday. The **C** chocolates are distributed among **N** students equally, and the remaining **R** chocolates are given back to Bala. Write a program for the same.

Example :
if C=100 and N=40, each student receive 2 chocolates, and the balance 100-40*2=20 is given back to Bala.

Input format :

The first line of input consists of the integer number of chocolates C.
The second line of input consists of the integer number of students N.

Output format :

The output prints the number of remaining chocolates, R.

Fill your code here

Pytho

```python
# You are using Python
C=int(input())
N=int(input())
d=C //N
res=C-(N*d)
print(res)
```

Single File Programming Question

Problem Statement

The room that Patrick and Johnny were staying in was very big. They felt too lazy to walk from the bed to another location. So they wanted to change the position of the bed. The shape of the room is a Square. They decided to place the bed at the exact center of the room so that their walking distance would be minimized. Can you help them place the bed at the exact center?

Given the coordinates of the left bottom vertex of the square room and the length of the side, you need to write a program to determine the coordinates of the center of the room.

Note: The Length of the side is always even.

Input format :

The first line of input consists of the integer **M,** which is the x-coordinate of the left bottom vertex of the square room.

The second line of input consists of the integer **N**, which is the y-coordinate of the left bottom vertex of the square room.

The third line of input consists of the integer **L**, which is the length of the side of the square room.

Fill your code here

Python ...

```python
# You are using Python
x=int(input())
y=int(input())
l=int(input())
L=l // 2
centre_x= x+ L
centre_y= y+L
print(f"The centre of the room is at ({centre_x},{centre_y})")
```

Problem Statement

Anbu runs a shop near a school and hence sells a lot of pencils. Anbu wants to write a program to find the number of pencils sold every day. The program will accept th number of pencils at N at the beginning of the day and the number of pencils at E at the end of the day(N>=E). The program must print the number of pencils sold on th particular day.

Input format :

The first line of input consists of an integer **N** representing the number of pencils at the beginning of the day.

The second line consists of an integer **E** representing the number of pencils at the end of the day.

Output format :

The output prints the number of pencils sold on that day.

Refer to the sample output for formatting specifications.

```python
# You are using Python
N=int(input())
E=int(input())
sold=N-E
print(sold)
```
